1. Problem Statement:

We wish to use PyGame to simulate a simplified 2D robot and perform state estimation using a Kalman Filter. The Motion Model is defined as follows:

$$\dot{x} = \frac{r}{2} (u_r + u_l) + w_x, \dot{y} = \frac{r}{2} (u_r + u_l) + w_y \quad (1)$$

In equation (1), $r = 0.1$ m, is the radius of the wheel, u_r and u_l are control signals applied to the right and left wheels. Additionally, $w_x = N(0, 0.1)$ and $w_y = N(0, 0.15)$.

We wish to simulate the system such that the robot is driven 1 m to the right. We are to assume the speed of each wheel is fixed at $0.1 \frac{m}{s}$. We use the following initial values:

$$x_0 = 0, y_0 = 0, P_0 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \text{ (initial covariance matrix)} \quad (2)$$

Also, we are to assume that the motion model is computed 8 times a second. We assume every second a measurement is given:

$$z = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} + \begin{bmatrix} r_x & 0 \\ 0 & r_y \end{bmatrix} \quad (3)$$

Where $r_x = N(0, 0.05)$ and $r_y = N(0, 0.075)$.

We wish to plot and animate the trajectory along with covariance ellipse for all motion models and measurement updates. We also aim to report what happens when a measurement arrives. We should note to discretize the system: $\dot{x} = \frac{(x_k - x_{k-1})}{T}$ where T is 1/8 sec. In the animation, we will show both ground-truth and estimates.

Solution Formulation: From the discretized system model we have:

$$\begin{bmatrix} x_k \\ y_k \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_{k-1} \\ y_{k-1} \end{bmatrix} + \begin{bmatrix} \frac{r_x}{2} & 0 \\ 0 & \frac{r_y}{2} \end{bmatrix} \quad (4)$$

where $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = A$ is our *state transition matrix*. Since the discretized system is formulated as follows:

$$\begin{aligned} \frac{x_k - x_{k-1}}{T} &= \frac{r}{2} (u_{r,k} + u_{l,k}) + w_{x,k} \\ x_k &= x_{k-1} + \frac{r}{2} (u_{r,k} + u_{l,k}) T + w_{x,k} T \\ \frac{y_k - y_{k-1}}{T} &= \frac{r}{2} (u_{r,k} + u_{l,k}) + w_{y,k} \\ y_k &= y_{k-1} + \frac{r}{2} (u_{r,k} + u_{l,k}) T + w_{y,k} T \end{aligned} \quad (5)$$

Comparing this with the general form $\mathbf{x}_k = A\mathbf{x}_{k-1} + B\mathbf{u}_k + \mathbf{w}_k$, we can identify the *control matrix* B as

follows:

$$B = \begin{bmatrix} \frac{r}{2}T & \frac{r}{2}T \\ \frac{r}{2}T & \frac{r}{2}T \end{bmatrix} \quad (6)$$

Note that in the general form, $\mathbf{u}_k = \begin{bmatrix} u_{r,k} \\ u_{l,k} \end{bmatrix}$ and $\mathbf{x}_k = \begin{bmatrix} x_k \\ y_k \end{bmatrix}$.

To determine the *process noise covariance matrix*, Q , of the system, we need to consider the variances of the individual process noise components:

$$Q = \begin{bmatrix} \text{Var}(w_x) & 0 \\ 0 & \text{Var}(w_x) \end{bmatrix} = \begin{bmatrix} 0.1 & 0 \\ 0 & 0.15 \end{bmatrix} \quad (7)$$

Similarly, from the measurement/observation model's general form of $\mathbf{z} = C\mathbf{x} + \mathbf{n}$, the *measurement noise covariance matrix*, R , of the system is as follows:

$$R = \begin{bmatrix} 0.05 & 0 \\ 0 & 0.075 \end{bmatrix} \quad (8)$$

Additionally, we deduce the *observation matrix*, C , to be:

$$C = \begin{bmatrix} 1 & 0 \\ 0 & 2 \end{bmatrix} \quad (9)$$

Thus, the formulation of system equation for the motion model in discrete time is as follows:

$$\begin{bmatrix} x_k \\ y_k \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_{k-1} \\ y_{k-1} \end{bmatrix} + \begin{bmatrix} \frac{r}{2}T & \frac{r}{2}T \\ \frac{r}{2}T & \frac{r}{2}T \end{bmatrix} \begin{bmatrix} u_{r,k} \\ u_{l,k} \end{bmatrix} + \begin{bmatrix} w_{x,k} \\ w_{y,k} \end{bmatrix} T \quad (10)$$
